Housing and Transportation Affordability Initiative

Introduction

The Location Affordability Portal (LAP), launched by the U.S. Department of Housing and Urban Development (HUD) and Department of Transportation (DOT) in November 2013, provides robust, standardized household housing and transportation cost estimates at the Census block-group level for the vast majority of the United States. These estimates are generated using the *Location Affordability Index Model* (LAIM Version 1), a combination of statistical modeling and data analysis using data from a number of federal sources. They are presented on the site in the form of two data tools: the Location Affordability Index (LAI), which visually represents outputs for eight different household profiles in the form of a national map, and My Transportation Cost Calculator (MTCC), which takes user-input information on household income, size, and number of workers and uses the LAIM to generate customized transportation cost estimates using the household's tenure, cars, employment locations, and travel patterns.

The *Location Affordability Index Model Version 2* (LAIM Version 2) represents a significant a methodological and technical advance from LAIM Version 1, in addition to updating all of the constituent data sources. LAIM Version 1 estimated three variables for transportation behavior (auto ownership, auto use, and transit use) and housing costs for homeowners and renters using separate Ordinary Least Squares (OLS) regression models. In LAIM Version 2, however, auto ownership, housing costs, and transit usage for both homeowners and renters are modeled concurrently using simultaneous (or structural) equation modeling (SEM) to capture the interrelationship of these factors.¹ The inputs to the SEM model include these six endogenous variables and 15-18 exogenous variables. ~~To hone in on the built environment's influence on the balance between transportation and housing costs, the exogenous household variables (income, household size, and commuters per household) are set at fixed values (i.e., the "selected household") in the Model's outputs to control for any variation they might cause. By establishing and running the model for a "selected household," any variation observed in housing and transportation costs may be attributed to place and location, rather than household characteristics.~~

Version 2 Model Development

During beta testing of the LAP Version 1 and subsequent discussions prior to the site's public launch², a number of reviewers suggested that the LAIM Version 1 could potentially be enhanced if the model was able to account for interaction effects.

Many advances in statistics have enabled the creation of more nuanced and sophisticated models for explaining urban phenomena along these lines. One approach that has gained currency in urban planning studies is a simultaneous (or structural) equation model (SEM). For a set of related OLS models, an SEM approach allows the dependent (left-side) variables for one or more regression equations to be included as independent (right-side) variables in other regression equations if these other independent variables could be expected to impact that equation's output. This approach has clear utility for the LAI Model, which uses a specific set of independent variables describing the built environment and

¹ Limited data on ~~vehicle miles traveled (VMT)~~ did not allow for its inclusion in the SEM; it continues to be modeled in Version 2 using OLS.

² For complete documentation of ~~LAIM Version 1 development~~, please see <http://www.locationaffordability.info/LAPMethodsV1.pdf> ~~"xxxx"~~ at url.

Commented [JMG1]: Move or delete

Commented [PH2]: Moved to introduction of:
Using the LAIM to Generate the Location Affordability Index (LAI)
Since this is so central to everything in the LAI, and is often missed.

Housing and Transportation Affordability Initiative

demographics to predict a number of interrelated transportation behaviors and housing costs. SEM better incorporates and accounts for interaction effects on the model's dependent variables, resulting in a model that has greater econometric validity.

The development process for LAIM Version 2 was highly iterative: many proposed models were tested and discarded for a variety of reasons, but each estimated model provided information. The final model used for LAIM Version 2, like all models, is not a perfect representation of reality. However, it is the best attempt to balance two competing goals: an explanatory model that highlights key interactions between variables, and a predictive model that can be employed to power the website data tools. Given these two goals, improved predictivity was to some extent prioritized at the expense of parsimony.

The final SEM includes endogenous variables housing costs, automobile ownership, and transit usage for both homeowners and renters as well as ~~45-18~~ exogenous variables. Auto use ~~or~~ annual vehicle miles traveled (VMT) continues to be modeled using OLS because ~~the data on VMT data is limited to data obtained only available~~ from the State of Illinois, and it does not distinguish ~~from between~~ auto owners who rent versus those who own their home.

I. Advances in LAIM Version 2

LAIM Version 2 uses both more sophisticated modeling and a refined set of variables that do a better job of representing the characteristics of the built environment relevant to housing and transportation costs.

A. Model Refinements

The use of the SEM, as well as additional development work, led to two innovations in the model structure as enumerated below.

1. **Model Integration:** The power of the SEM was leveraged to reduce the number of necessary models. The new model structure allows a single model to predict housing costs, auto ownership levels, and transit commute mode shares rather than having separate equations for each. This is the inherent benefit of the SEM (~~As previously noted, vehicle miles traveled (VMT)/VMT~~ continues to be calculated separately as limited data are available).
2. **Model Comprehensiveness:** The combination of the SEM approach and the refined variables allowed development of a single model for the entire nation³ rather than separate models for urban and rural areas. This was achieved by focusing on county level data rather than CBSA data for rural counties and taking advantage of the feedback inherent in SEM to use the share of transit commuters as a proxy variable for transit service levels. Previously, the model was split between areas where transit service levels were known and areas where transit service levels were unknown. SEM allows transit mode share to be simultaneously an explanatory and a response variable. The reduction in the number of input (exogenous) variables reduces the goodness of fit for the places where explicit transit supply data was available, but enhances the simplicity of the model, making it possible to develop only one model for all census block groups (both urban and rural) for the entire country.

Commented [JG3]: This footnote will be expanded – CNT

Commented [NB4R3]: CNT moved the footnote...See footnote 6, page 15.

³~~Excluding Massachusetts, which does not participate in the LEHD.~~

B. Variable Refinements

During the development of LAIM Version 2, the original set of variables was reconsidered and refined as possible. A short description of these refinements follows.

1. **Local Amenities:** Local job measures were developed as a proxy for local amenities. This information is helpful in determining whether one could live in an area without a car and still have access to basic needs, such as shopping.
2. **Income Scaling:** A variable that scales income based on the regional median income within Core Based Statistical Areas (CBSAs) and the county median income in rural areas outside of a CBSA. This adjustment improves the ability to offer an “apples-to-apples” comparison of purchasing power, particularly for auto-ownership decisions. It is also the relevant median income within the model ~~to that~~ appropriately estimate housing expenses based on the local market. ~~Suggested by HUD, this “mixed” approach, using the regional median for CBSAs and the county median for rural areas, fits the data better than a simple CBSA or the county-based approach used in an earlier SEM iteration.~~
3. **Housing Characteristics:** Housing stock data, specifically percent of single-family detached housing units and the number of rooms per dwelling unit by occupied tenure, were incorporated into the model.
4. **Tenure Split:** Population data was split based on whether the respondents own or rent their residence. This affects variables tied to people (household size, income, transit mode shares, etc.), but not those tied to the surrounding environment (household density, job density, etc.). The resulting model structure provides added insight into the decisions of renters and owners although it reduces the predictive power of the overall model by a few percentage points. However, given the strong theoretical justification for considering renters and owners separately, it was decided to include this split in the final model.

II. Model Specification

A. Endogenous Variable Interactions

The first step in developing an SEM is to develop the model specification, using a set of hypotheses that illustrate the relationship between the various input variables. The endogenous variables (below) are each predicted by individual regression models nested within the SEM and are all interrelated:

- Autos/Household Owners
- Autos/Household Renters
- Gross Rent
- Selected Monthly Ownership Costs (SMOC)
- Transit Percent Journey to Work (%J2W) Owners
- Transit %J2W Renters

~~Figure 1~~ ~~Figure 1~~ is a schematic representation of the ~~hypotheses-relationships~~ that ~~drive~~ the decision to add feedback in the SEM between the endogenous variables. ~~The arrows with two heads indicate that in principle, causality can go either both ways.~~ In the actual implementation, it was found that once

Formatted: Font: Not Bold

Housing and Transportation Affordability Initiative

causality is explained in one direction, the other direction is either not statistically significant or markedly less significant, and the goodness of fit is reduced. For example, having SMOC in the homeowner auto ownership equation obviates the need for putting homeowner auto ownership into the SMOC equation. The one exception to this is the interaction between owner and renter transit use; in these cases, both interactions were found to be important and thus were included in the final model (noted by the double headed arrow). [Table 1](#) [Figure 2](#), following the schematic, shows the hypothesis and the relationships in the final model. ~~The~~ interactions are limited to only those of the same tenure, unless the endogenous variables are of the same behavior (i.e., Auto Use by Owners interacts with Auto Ownership by Renters but not [with](#) Transit %J2W Renters or [Gross Rent](#)).

Figure 1: Possible Representation of the Relationships between the Endogenous Variables Implemented in the SEM

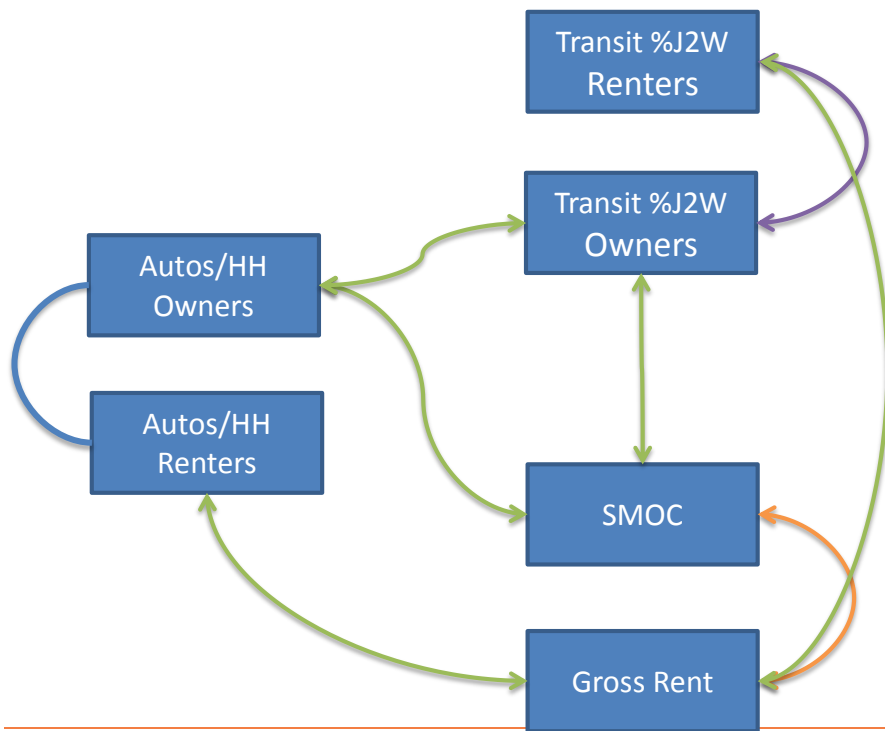

Table 1: Hypothesis of Endogenous Variable Interactions

Variable 1 (V ₁)	Variable 2 (V ₂)	Hypothesis	Interaction Used
Autos/Household Owners	Autos/Household Renters	Auto ownership is driven by the same factors independent of tenure. So the correlation observed here is coincidental and not causal. Therefore no explicit connection used in model.	None
Autos/Household Owners	SMOC	Auto ownership and housing costs are both very large components of the a household's budget. Thus these two measures are in-total constrained by the at budget and are thus very dependent on one another.	One Way (V ₂ → V ₁)
Autos/Household Owners	Transit %J2W Owners	Auto ownership and transit use are obviously related.	One Way (V ₁ → V ₂)
Autos/Household Renters	Gross Rent	Auto ownership and housing costs are both very large components of the a household's budget. Thus these two measures are in-total constrained eded by the at budget and are thus very dependent on one another.	One Way (V ₂ → V ₁)
Autos/Household Renters	Transit %J2W Renters	Auto ownership and transit use are obviously related.	One Way (V ₁ → V ₂)
SMOC	Gross Rent	Local housing market conditions depend on household formation, interest rates, household net worth, labor market conditions and other fundamental factors such as housing stock. In some models, these fundamental factors determine long run equilibrium housing costs as reflected in rental costs, while short run ownership costs fluctuate around long run equilibrium (rental) values, with short run fluctuations driven in part by the inventory/sales ratio.	One Way (V ₁ → V ₂)
SMOC	Transit %J2W Owners	Unlike the relationship between housing cost and auto ownership, the cost of transit is relatively low thus the constraint driven by the a household's budget is less rigid. Therefore there is no t strong reason for a interaction and none observed.	None
Gross Rent	Transit %J2W Renters	Unlike the relationship between housing cost and auto ownership, the cost of transit is relatively low thus the constraint driven by the a household's budget is less rigid. Therefore there is no t strong reason for a interaction and none observed.	None

Formatted Table

Variable 1 (V ₁)	Variable 2 (V ₂)	Hypothesis	Interaction Used
Transit %J2W Owners	Transit %J2W Renters	Transit use is driven by the same factors independent of tenure. So the correlation observed here is driven by non-measured exogenous variables. Since in this model there is no transit supply or access measure, this interaction provides-serves as a surrogate.	Two Way

Formatted Table

B. Variable Transformation

Once relationships between endogenous variables have been hypothesized, a preliminary model can be constructed. ~~with As in the previous model~~ In LAIM Version 2, SEM variables ~~have been are~~ transformed to allow for better fits for non-linear relationships. As shown in ~~Figure 2~~ Figure 3 (below), a typical approach to transforming variables ~~was used. It is the same approach for this iteration of the model is the same~~ as that used in the original LAIM, i.e., pick the transformation that produces the most normal distribution for each variable – both the endogenous and exogenous. The graphs in ~~Figure 2~~ Figure 3 represent an example for median gross rent. The components of the figure are described below:

- Purple bars represent ACS data
- Red bars represent a Gaussian (or normal) distribution with the same mean and standard deviation as the census data
- The “Normal R2” value is coefficient of determination of the ACS data to the normal distribution.

Figure 2: Example of Linear Transformation

By evaluating the exogenous variables to observe how non-linear the relationships between them are, a transformation is chosen to reduce non-linear effects. ~~For this iteration of the model~~ In the SEM approach used in LAIM Version 2, the transportation endogenous variables ~~have were not been~~ transformed; ~~however,~~ housing costs variables (gross rent and SMOC) ~~have been are~~ transformed using the natural log as in LAIM Version 1.

Autos/HH Owners	Linear	1.949	0.421
Autos/HH Renters	Linear	1.353	0.492
Gross Rent	Natural Log	6.727	0.386
SMOC	Natural Log	7.231	0.391
Transit %J2W Owners	Linear	3.814	10.053
Transit %J2W renters	Linear	6.012	14.008

J2W = Journey to Work

HH = Households

HU = Housing Units

SMOC = Selected Monthly Ownership Costs

⁵ When the mean is less than zero it is overwritten with 1.0 to make interpretation more direct.

NOTE: Endogenous variables shaded.

After being transformed, all variables were standardized so that the SEM function in R⁴ would be able to handle the wide variation in values. To standardize, the mean of the transformed variable was subtracted by the mean of the transformed variable's distribution; from each data point and then this

⁴ R is a software programming language used for statistical analysis.

difference was then scaled by one over the standard deviation of the entire distribution. The resulting variable (Z), i.e. the fit variables used in the SEM analysis is:

$$Z = \frac{f - \bar{f}}{StDev}$$

$$v = \frac{f - \bar{f}}{StDev}$$

~~where~~Where f is the transformed variable, \bar{f} is the mean of the distribution of f and $StDev$ is the standard deviation of the distribution of f .

This standard score (Z) of each variable was applied to enable the SEM function in R⁵ to handle the wide variation in values. However, ~~this standardization has the two added advantage of making the model more transparent as there is no need for an intercept in the regression equation and it eliminates the for an intercept in the regression equation and it allows the coefficients themselves to relate directly to reflect the change expected in the transformed endogenous variable when the transformed exogenous variable is changed by one standard deviation, thus making the model more transparent.~~

Commented [JMG5]: Unclear needs better explanation

C. Variable Selection

The following table ~~Table 3~~ lists the variables used in the original LAIM but dropped from ~~this analysis~~LAIM Version 2.

Formatted: Indent: Left: 0"

Table 3: LAIM Version 1 Variables ~~in Original LAI~~ Dropped in Latest Version of the LAILAIM Version 2

Dropped Variable	Description	Reason for Dropping
Residential Density	# of households in residential blocks	Highly correlated with gross density, which was a Gross density measure can we could be obtained annually from the ACS rather than relying on decennial census for Residential Density .
Intersection Density	# of intersections / total land area	Encapsulated by other measures of local walkability/density (See section on Street Connectivity and Walkability below)
Transit Connectivity Index	Transit access as a function of transit service frequency and proximity to transit nodes, weighted by observed journey to work data	Replaced by transit commute share, a measure <u>available</u> for the entire country.
Transit Access	Shed Optimal accessible area by public transportation within 30 minutes and one transfer	Ibid

⁵ R is a software programming language used for statistical analysis.

Housing and Transportation Affordability Initiative

Dropped Variable	Description	Reason for Dropping
Transit Frequency of Service	Service frequency within a Transit Access Shed	Ibid
Job Diversity Index	Function of the correlation between employment in 20 different industry sectors and autos per household	Job diversity was determined to not seen-as-be the best measure of local transit amenity; replaced with a count of actual local jobs.
Median Selected Monthly Owner Costs	Includes mortgage payments, utilities, fuel, and condominium and mobile home fees where appropriate	Median area SMOC does is not as strong a predictor of regional markets so it capture the variation found in local SMOC; was replaced with the area (CBSA or County for rural areas) county median income.
Median Gross Rent	Includes contract rent as well as utilities and fuel if paid by the renter	Ibid
Median household income		Replaced by scaled income (see point 2 on page 545 of this document)

Commented [JG6]: As discussed, we need a better explanation here. I tried and failed to write one.

After discussion with HUD staff and a literature review, variables listed in Table 4 ~~on the following page~~ were added to the model [based on feedback from HUD staff and a literature review of rural VMT.](#)

Table 4: Variables Added for the SEM/Rural Analysis

Added Variable	Description	Reason for Adding
Area Median HH Income	Median county household income for counties in Rural (non CBSA) areas, and CBSA Median household income for those within a CBSA.	To scale for regional market variations in housing cost.
Fraction Rental Units	Number of rental occupied housing units divided by all occupied housing units.	To adjust for different housing stock and use.
Local Retail Jobs per acre	Number of retail jobs within half mile of centroid divided by land area of same.	Access to retail amenities.
Local Job Density	Number of jobs within half mile of centroid divided by land area of same.	Local job access.
Median Rooms/Owner HU	Median number of rooms in housing units for owner occupied units.	Indicator of local ownership housing stock size.
Median Rooms/Renter HU	Median number of rooms in housing units for renter occupied units.	Indicator of local rental housing stock size.
Fraction Single Detached HU	Number of housing units in single family detached buildings.	Indicator of local housing type.
Retail Gravity	Same as employment gravity but only for retail jobs.	Access to regional retail amenities.

Housing and Transportation Affordability Initiative

Added Variable	Description	Reason for Adding
Income/Area Income Owner	Median household income divided by county median income for occupied owner housing units in Rural (non CBSA) areas and by CBSA Median income for those within a CBSA.	Scaled income (see point 2 on page 545 of this document).
Income/Area Income Renter	Median household income divided by county median income for occupied owner occupied housing units in Rural (non CBSA) areas and by CBSA Median income for those within a CBSA.	Ibid

Formatted: Keep with next

D. Final Fit

The following section describes in detail final model's specification and all included variables.

LAIM Version 2 Methodology

I. Geographic Level and Data Availability

LAIM Version 2 is constructed at the Census block group level using the 2012 American Community Survey (ACS) 5-year estimates as the primary dataset. This is the predominant source for input parameters and measured data for the dependent variables. The LAIM Version 2 is constructed to cover the entire United States⁶.

II. Basic Index Structure

LAIM Version 2 employs a SEM regression analysis for [auto ownership, transit use and housing costs](#) and a second order flexible form of ordinary least squares (OLS) model for VMT is used for LAIM Version 2. ~~six out of eight predicted variables.~~ It allows for all of the input variables to be used in the calculation of the coefficients. This somewhat complex modeling technique is employed to better model interactions between the endogenous variables. The goodness of fit is now measured by a combination of measures [rather than by a simple R-squared value](#) (see [Section A.V. Model Structure and Formula, A-iii-vii.](#) on goodness of fit measures on page ~~292424~~ for further discussion) ~~rather than by a simple R-squared value.~~ Additionally, ~~To~~ To keep the model as simple as possible, input measures of transit access are no longer used. ~~However~~ However since two endogenous variables are themselves measure of transit use (i.e., percent of commuters using transit for journey to work for home-owners and renters), the model works well. [These revisions allow](#)

LAIM Version 2 ~~is to a model of~~ is a model of housing and transportation costs by tenure for households in urban, suburban, and rural settings. ~~LAIM Version 2 uses a second order flexible form of OLS for the VMT model. In other words it is uses one model for VMT for the entire country, and uses SEM for auto ownership, transit use and housing costs.~~

⁶ There are a few block groups in the United States that do not have households in them, these are not modeled.

Housing and Transportation Affordability Initiative

III. Data Sources

LAIM Version 2 is produced from data drawn from a combination of the following Federal sources:

- U.S. Census American Community Survey (ACS) – an ongoing survey that generates data on community demographics, income, employment, transportation use, and housing characteristics. 2008-2012 survey data are used in LAI Version 2.
- U.S. Census TIGER/Line Files – contains data on geographical features such as roads, railroads, and rivers, as well as legal and statistical geographic areas.
- U.S. Census Longitudinal Employment-Household Dynamics (LEHD) Origin-Destination Employment Statistics (LODES) – detailed spatial distributions of workers' employment and residential locations and the relation between the two at the Census Block level, including characteristic detail on age, earnings, industry distributions, and local workforce indicators (see overview). LODES and OnTheMap Version 7, which are built on 2010 Census data, are used here.

These data describe relevant characteristics of every census block group in the United States. Census block groups contain between 600 and 3,000 people and vary in size depending on an area's population density. They range from only a few city blocks to the entirety of some rural counties. Block groups are the smallest geographical unit for which reliable data is available; they can generally be thought of as representing neighborhoods.

IV. Variables

Starting with a pool of potential independent ([exogenous in the SEM](#)) variables representing all of the possible influences on housing and transportation costs for which data were available, exogenous variables for the model were chosen according to the strength of their correlation with the endogenous variables and their statistical significance. The choice of variables for LAI Version 2 builds on the theoretical framework developed for LAI Version 1 with federal stakeholders and the technical review panel. [Table 5](#) lists the final set of variables used in LAI Version 2, with endogenous variables shaded.

Table 5: Overview of [LAIM Version 2](#) Variables

Input	Description	Data Source
Gross Density	# of households (HH) / total acres	Census ACS, TIGER/Line files
Block Density	# of blocks / total land area	Census TIGER/Line files
Employment Access Index	Number of jobs in area block groups / squared distance of block groups	Census LEHD-LODES
Retail Employment Access Index	Number of retail jobs in area block groups / squared distance of block groups	Census LEHD-LODES
Median Commute Distance	Calculated from data on spatial distributions of workers' employment and residential locations and the relation between the two at the Census block level	Census LEHD-LODES
Job Density	# of jobs / total land area	Census LEHD-LODES
Retail Density	# of retail jobs / total land area	Census LEHD-LODES
Fraction of Rental	Number of rental units as a percentage of total housing	Census ACS

Housing and Transportation Affordability Initiative

Input	Description	Data Source
Units	units	
Fraction of Single Family Detached Housing Units	Number of single family detached housing units as a percentage of total housing units	Census ACS
Median Rooms/Owner HU	Median number of rooms in owner occupied housing units (HU)	Census ACS
Median Rooms/Renter HU	Median number of rooms in renter occupied housing units	Census ACS
Area Median Household Income	Determined using County median household income for rural areas or CBSA median household income for Metropolitan and Micropolitan Areas	Census ACS
Fraction of Median Income Owners	Median income for owners at the block group level as a percentage of either CBSA or County median income (County for rural areas / CBSA for Metropolitan and Micropolitan Areas)	Census ACS
Fraction of Area Median Income Renters	Median income for renters at the block group level as a percentage of either CBSA or County median income (County for rural areas / CBSA for Metropolitan and Micropolitan Areas)	Census ACS
Average Household Size: Owners	Calculated from data on Tenure and Total Population in Occupied Housing Units by Tenure	Census ACS
Average Household Size: Renters	Calculated from data on Tenure and Total Population in Occupied Housing Units by Tenure	Census ACS
Average Commuters per Household Owners	Calculated using the total number of workers 16 years and over who do not work at home	Census ACS
Average Commuters per Household Renters	Calculated using the total number of workers 16 years and over who do not work at home	Census ACS
Median Selected Monthly Owner Costs	Includes mortgage payments, utilities, fuel, and condominium and mobile home fees where appropriate	Census ACS
Median Gross Rent	Includes contract rent as well as utilities and fuel if paid by the renter	Census ACS
Autos per Household Owners	Calculated from Aggregate Number of Vehicles Available by Tenure and Occupied Housing Units	Census ACS
Autos per Household Renters	Calculated from Aggregate Number of Vehicles Available by Tenure and Occupied Housing Units	Census ACS
Percent Transit Journey to Work Owners	Calculated from Means of Transportation to Work by Tenure	Census ACS
Percent Transit Journey to Work Renters	Calculated from Means of Transportation to Work by Tenure	Census ACS

Housing and Transportation Affordability Initiative

The following detailed descriptions of variables used for LAIM Version 2 are organized according to the seven largest factors that influence transportation costs: density; connectivity and walkability; employment access and diversity; housing characteristics; individual household characteristics; housing costs; and household travel behavior. [Appendix A: Appendix A:](#)

~~Scatter Plots of Endogenous Variables vs. an Example Exogenous Variable~~
~~Scatter Plots of Endogenous Variables vs. an Example Exogenous Variable~~
~~Scatter Plots of Endogenous Variables versus an Example Exogenous Variable~~ show some of the relationships of the endogenous and exogenous variables.

A. Household Density

Household density has been found to be one of the largest factors in explaining the variation in all three transportation dependent variables. Various definitions of density have been constructed and tested, and the following two have been utilized in modeling both housing and transportation costs.

i. Gross Density

Gross Density is calculated as total households (from the ACS) divided by total land acres (calculated using TIGER/Line files).

B. Street Connectivity and Walkability

Measures of street connectivity have been found to be good proxies for pedestrian friendliness and walkability. Greater connectivity created by numerous streets and intersections creates smaller blocks and tends to lead to less dependence on automobiles as well as shorter average auto trips, and more use of transit. While other factors clearly have an impact on the pedestrian environment (e.g., crime), the following measure of street connectivity has been found to be an important driver of auto ownership, auto use, and transit use.

i. Block Density

Census TIGER/Line files are used to calculate average block density (in acres) using the number of blocks within the block group divided by the total block group land area. [Although LAIM Version 1 used a combination of block density and intersection density, in LAIM Version 2 the only measure of street connectivity and walkability used in LAIM Version 2 is block density.](#) ~~in LAIM Version 2, Version 1 used a combination of block density and intersection density.~~ The addition of intersection density created a model that ~~was~~ slightly better in terms of prediction, but because of the very high co-linearity between these two measures, it made the model less transparent. Since block density improves the SEM model more than intersection density, block density was chosen to be included in LAIM Version 2. [Figure 3](#) ~~Error! Reference source not found.~~ ~~Error! Reference source not found.~~ ~~below,~~ [which](#) shows the correlation between these ~~two~~ measures, ~~showing~~ [illustrates](#) just how collinear these two measures are.

C. Employment Access and Diversity

Employment numbers are calculated using OnTheMap Version 7 which provides Longitudinal Employer-Household Dynamics (LEHD) Origin Destination Employment Statistics (LODES) at the Census block group level. These data are currently unavailable in Massachusetts.⁷

Measures of employment access and density provide not only an examination of access to work, but are good surrogates for proximity to economic activity. While they overlap in what they measure, each have a unique aspect that make them more predictive when used in concert, than when used individually.

i. Employment Access Index

The Employment Access Index is determined using a gravity model which considers both the quantity of and distance to all employment destinations, relative to any given block group. Using an inverse-square law, an employment index is calculated by summing the total number of jobs divided by the square of the distance to those jobs. This quantity allows for the examination of both the existence of jobs and the accessibility of these jobs for a given Census block group. Because a gravity model enables consideration of jobs both directly in and adjacent to a given block

⁷ Excluding Massachusetts, which does not participate in the LEHD. Using Massachusetts ES202 database query tool (http://lmi2.detma.org/lmi/lmi_es_a.asp) the employment by county was obtained for 20140. Using a constant share method from the 2000 CTPP employment data at the block group level, an estimate of 20140 employment was made for every block group in Massachusetts.

Housing and Transportation Affordability Initiative

group, the employment access index gives a better measure of job opportunity, and thus a better understanding of job access than a simple employment density measure. This index also serves as a surrogate for access to economic activity.

The Employment Access Index is calculated as:

$$E \equiv \sum_{i=1}^n \frac{p_i}{r_i^2}$$

Where

E = Employment Access for a given Census block group

n = total number of Census block groups

p_i = number of jobs in the i^{th} Census block group

r_i = distance (in miles) from the center of the given Census block group to the center of the i^{th} Census block group

As jobs get farther away from the Census block group their contribution to the Employment Access Index is reduced; for example, one job a mile away adds one, but a job 10 miles away adds 0.01. All jobs in all U.S. Census block groups are included in this measure.

ii. Retail Employment Index

This index is calculated using the same method as the Employment Access Index (above) only using the number of jobs in NAICS sector 44-45 (Retail Trade)

iii. Median Commute Distance

Median commute distance is calculated using LODES data. Median distances are calculated for each Census block using Euclidean (as the crow flies) distances between the origin and destination Census blocks. Block values are then sorted by distance to obtain the median value for the block group of interest.

Housing and Transportation Affordability Initiative

iv. Local Job Density

Three different steps are considered to determine local job density, all of which use a half-mile buffer around the centroid of each block group (the centroid in this case, is defined by the average of the block centroids weighted by households from 2010 Census). Using LODES data, the total number of jobs in the buffer is calculated and divided by the land area. The jobs and land is derived in one of three ways depending on the size of the block group. Figure 4 on the following page illustrates three possible scenarios:

- a. If the border of the block group is completely within the half-mile buffer zone, the half-mile buffer value is used;
- b. If the union⁸ of the half-mile buffer and block group polygons are about the same, the value is determined by the polygon; or
- c. If the half-mile buffer is completely inside the block group, the block group value is used.

Figure 4 on the following page illustrates three possible scenarios.

Formatted: Indent: Left: 0"

⁸ "Union" is a GIS term which refers to the merging of two polygons into one. All three steps used to determine employment and retail density use the "union" of two polygons: the half-mile buffer and the block group.

Figure 4: Three Scenarios Considered for Local Employment Density Measures

v. Local Retail Density

The same three steps used to determine local job density are used for local retail density. After constructing a half-mile buffer around the centroid of each block group, LODES data is used to calculate the total number of retail jobs in the buffer, which is then divided by the land area.

- If the border of the block group is completely within the half-mile buffer zone, the half-mile buffer value is used;
- If the union⁹ of the half-mile buffer and block group polygons are about the same, the value is determined by the polygon; or
- If the half-mile buffer is completely inside the block group, the block group value is used.

Again, Figure 4 illustrates the three possible scenarios.

D. Housing Characteristics

Characteristics of the housing stock and tenure have been found to have an effect on household travel behavior. Fraction of Rental Units serves as a measure of tenure within a neighborhood. The model incorporates data on housing stock, specifically percent of single-family detached housing units, to further understand the impact of the built environment on transportation decisions. The 2012 ACS 5-year estimates serve as the data source for variables pertaining to housing characteristics.

⁹ "Union" is a GIS term which refers to the merging of two polygons into one. All three steps used to determine employment and retail density use the "union" of two polygons: the half-mile buffer and the block group.

Housing and Transportation Affordability Initiative

i. Fraction of Rental Units

Using data on Tenure from the ACS, the number of rental units as a percentage of total housing units is calculated.

ii. Fraction of Single Family Detached Housing Units

Using data Tenure by Units in Structure from the ACS, the number of single-family detached housing units as a percentage of total housing units is calculated.

iii. Number of Rooms in Owner Occupied Housing Units

Data on Median Number of Rooms by Tenure is determined from the ACS, and is included as an exogenous variable. In cases where the Median Number of Rooms in owner occupied households is suppressed, the value for the tract is used in running the model but not for calibrating the model.

iv. Number of Rooms in Renter Occupied Housing Units

Data on Median Number of Rooms by Tenure is determined from the ACS, and is included as an exogenous variable. In cases where the Median Number of Rooms in renter occupied households is suppressed the value for the tract is used in running the model but not for calibrating the model.

E. Household Characteristics

The 2012 ACS 5-year estimates serve as the primary data source for variables pertaining to household characteristics.

i. Area Median Income

Median household income is obtained directly from the ACS at the CBSA level for block groups in metropolitan and micropolitan area and at the county level for all other block groups.

ii. Fraction of Area Median Income Owners

Fraction of area median income for owners is calculated as the ratio of median income for owners at the block group level to the Area Median Income (see paragraph E.i.). In cases where the block group median income for owner occupied households is suppressed, the value for the tract is used in running the model but not for calibrating the model.

iii. Fraction of Area Median Income Renters

Fraction of area median income for renters is calculated as the ratio of median income for renters at the block group level to the Area Median Income (see paragraph E.i.). In cases where the block group median income for renter occupied households is suppressed, the value for the tract is used in running the model but not for calibrating the model.

iv. Average Household Size Owners

Average household size for owners is calculated using Tenure and Total Population in Occupied Housing Units by Tenure to define the universe of Owner Occupied Housing Units. The total population in owner units is divided by the number of owner units. In cases where the block group population in owner occupied households is suppressed, the value for the tract is used in running the model but not for calibrating the model.

Housing and Transportation Affordability Initiative

v. Average Household Size Renters

Average household size for renters is calculated using Tenure and Total Population in Occupied Housing Units by Tenure to define the universe of Renter Occupied Housing Units (see paragraph E. iv). In cases where the block group population in renter occupied households is suppressed the value for the tract is used in running the model but not for calibrating the model.

vi. Average Commuters per Household Owners

Average commuters per household is calculated using the total number of workers 16 years and older who do not work at home from Means of Transportation to Work and Tenure to define Owner Occupied Housing Units. Because Means of Transportation to Work includes workers not living in occupied housing units (i.e., those living in group quarters), the ratio of Total Population in Owner Occupied Housing Units to Total Population is used to scale the count of commuters to better represent those living in households. In cases where the block group population in owner occupied households is suppressed, the value for the tract is used in running the model but not for calibrating the model.

vii. Average Commuters per Household Renters

Average commuters per household is calculated using the total number of workers 16 years and older who do not work at home from Means of Transportation to Work and Tenure to define Renter Occupied Housing Units. Because Means of Transportation to Work includes workers not living in occupied housing units (i.e., those living in group quarters), the ratio of Total Population in Renter Occupied Housing Units to Total Population is used to scale the count of commuters to better represent those living in households (see paragraph E. vi). In cases where the block group population in renter occupied households is suppressed, the value for the tract is used in running the model but not for calibrating the model.

F. Housing Costs

The 2012 ACS 5-year estimates serve as the data source for variables pertaining to housing costs.

i. Median Selected Monthly Owner Costs

Median Selected Monthly Owner Costs are taken directly from the ACS and include mortgage payments, utilities, fuel, and condominium and mobile home fees, where appropriate.

ii. Median Gross Rent

Median Gross Rent is taken directly from the ACS and includes contract rent as well as utilities and fuel if paid by the renter.

G. Household ~~Travel~~Transportation Behavior

The 2012 ACS 5-year estimates serve as the data source for variables pertaining to household ~~travel~~transportation behavior.

i. Autos per Household Owners

Autos per Household Owners is calculated from Aggregate Number of Vehicles Available by Tenure and Occupied Housing Units.

Housing and Transportation Affordability Initiative

ii. Autos per Household Renters

Autos per Household Renters is calculated from Aggregate Number of Vehicles Available by Tenure and Occupied Housing Units.

iii. Percent Transit Journey to Work Owners

As no direct measure of transit use is available at the block group level, a proxy is utilized for the measured data to represent the variable of transit use. From the ACS, Means of Transportation to Work by Tenure is used to calculate a percent of commuters in owner-occupied housing utilizing public transit.

iv. Percent Transit Journey to Work Renters

As no direct measure of transit use is available at the block group level, a proxy is utilized for the measured data to represent the variable of transit use. From the ACS, Means of Transportation to Work by Tenure is used to calculate a percent of commuters in renter-occupied housing utilizing public transit.

V. Model Structure and Formula

A. Simultaneous Equations Model

As [previously](#) mentioned [above](#), the SEM used in LAIM Version 2 consists of [6-six](#) nested [OLS-](#) equations, each drawing from a pool of [15-18](#) exogenous [variables/variables](#), that predict [6-six](#) - interrelated endogenous variables.

i. SEM Structure

Table 6 shows the structure of the SEM model used in LAIM Version 2, organized by the six [OLS-nested](#) equations for the model's endogenous variables (which are shaded and bolded).- All endogenous variables appearing as exogenous variables in other [OLS-nested](#) equations are shaded as well.

Transit %J2W Owners	Autos/HH Owners	-0.215 +/- 0.002	As auto ownership goes up, transit ridership decreases for home owners.
Transit %J2W Owners	Transit %J2W Renters	0.321 +/- 0.006	As more owners use transit, more renters do as well.
Transit %J2W Renters	Autos/HH Renters	-0.172 +/- 0.002	As auto ownership goes up, transit ridership decreases for renters.
Transit %J2W Renters	Transit %J2W Owners	0.397 +/- 0.006	As more renters use transit, more owners do as well.

Formatted Table

Figure 5 and Figure 6 are different graphical representations of all 21 variables in the model. Note that green lines indicate a positive relationship (i.e., as Gross Household Density goes up, transit use increases) and red lines indicate a negative relationship (i.e., as Gross Household Density goes up auto ownership decreases). The width of the lines are symbolic of the strength of the relationship, with wider lines indicating a stronger relationship than narrow ones (i.e., area income is more strongly related to housing costs than to autos owned per household).

Figure 5: Path Diagram for SEM Model

Commented [JMG7]: As previously mentioned, these figures need keys so readers can better interpret the lines.

Commented [NB8R7]: Moved to the appendix

ii. Evaluation Metrics

The complexity of SEMs has resulted in a range of metrics to assess the model goodness of fit. For the particular SEM employed in LAIM Version 2, recommendations from R.B. Kline's *Principles and Practice of Structural Equation Modeling*, the standard text for SEMs, were followed ~~to~~ emphasizing three metrics:

1. **Root Mean Square Error of Approximation (RMSEA):** This metric measures error of approximation while accounting for sample size. ~~In other words, RMSEA~~ It is an estimate of the discrepancy between the model and the data compensating for degrees of freedom. The rule of thumb that Kline reports is that ~~an~~ "RMSEA \leq 0.05 indicates close approximate fit, values between 0.05 and 0.08 suggest reasonable error of approximation, and RMSEA \geq 0.10 suggests poor fit." A 90% confidence interval is commonly used to assess the range of the RMSEA score. The model has an RMSEA of 0.053 whose 90% confidence interval ranges from 0.052 to 0.054.
2. **Comparative Fit Index (CFI):** This index measures the improvement in fit compared to a baseline model that assumes no population covariances for the observed variables. ~~In other words the CFI~~ It analyzes the model fit examining the discrepancy between the data and the hypothesized model, while adjusting for the issues of sample size inherent in the chi-squared test of model fit. The rule of thumb that Kline reports is that CFI "values greater than roughly 0.90 may indicate reasonably good fit of the researcher's model." The model has a CFI of 0.970.
3. **Standardized Root Mean Square Residual (SRMR):** This metric compares residuals between the observed and predicted variable correlations. ~~In other words, SRMR~~ It is the square root of the discrepancy between the sample covariance matrix and the model covariance matrix. The rule of thumb Kline reports is that "values of the SRMR less than 0.10 are generally considered favorable." The model has an SRMR of 0.013.

~~By achieving these three robust measures, the SEM model used for LAIM Version 2 is shown to be a good statistical model. The LAI Version 2 SEM model is show with all three of these robust measures to be a good statistical model.~~

Formatted: List Paragraph, Indent: Left: 0.25"

B. Vehicle Miles Traveled

As noted previously, auto use or ~~vehicle miles traveled (VMT)~~ is not included in the SEM due to data limitations. For the dependent variable of auto use, the regression analysis was fit using data on the total number of miles households ~~that~~ drive their autos, calculated from odometer readings for 2008 through 2010 from the Chicago and St. Louis metro areas obtained from the Illinois Environmental Protection Agency. Two odometer readings—for 2008 and 2010—were matched for over 660,000 vehicles using vehicle identification numbers (VIN) to derive estimates for VMT during that period.

The geographic area that the data covers includes a variety of place types—from rural to large city—which provides excellent fodder for calibrating a model. ~~To ensure~~ The validity of this data set for the entire country ~~is ensured by examining~~ national driving records ~~were obtained~~ from the National Household Travel Survey (NHTS) and ~~assigned~~ assigning them to Census block groups using ZIP+4™ geographical identifications. Automobiles were matched using the vehicle VIN, and the total distance driven was determined over the time period between inspections. The resulting analysis showed that the final value of VMT should include an additional factor of eight percent. This factor compensates for the fact that the vehicles in this sample were all five years old or older. To reduce

any bias in the model, this factor is estimated by comparing the 2009 National Household Travel Survey (NHTS) to the modeled value of the NHTS field ANNMILES, which is the self-reported miles driven for each auto. [The ratio of the average VMT from the model LAI VMT model described here, and the average ANNMILES by census regions \(Mid-West, Northeast etc. were averaged for the large geography because of relatively small sample size of NHTS\) was 1.08. It is hypothesized that the full eight percent mostly compensates for the age of the vehicles; however, it should also compensate for, as well as any other bias that may occur from the limited data sample from Illinois used to calibrate the model.](#)

In [both versions of the LAIM](#), VMT is constructed using [Ordinary Least Squares \(OLS\)](#) regression analysis with a second order flexible functional form. This flexible form takes into consideration all the independent variables as well as the interaction between them, i.e., household density and household income are separate inputs; the combination of the two are also used as inputs. The independent variables used in the regression are the same as the exogenous variables for SEM and were linearized in the same way as in the SEM analysis. The choice of transformation was made to optimize the distribution of the variables such that the distribution of the transformed variable was the most Gaussian or Normal. All Census block groups covered by the Illinois odometer data [\(see previous section\)](#) were used for the auto use regression.

Additionally, because there is an inherent spatial autocorrelation for the dependent variables, a robust variance calculation is employed to estimate the statistical significance of the regression coefficients. The method for estimating the error on the coefficients uses geographical clustering. Three natural geographical clustering definitions were tested: state, county and CBSA. The testing showed that the errors estimate increased (as expected) when using this robust approach, and that the state clustering increased the error estimate the least, with the county and CBSA clustering having similar estimates; therefore the CBSA clustering was employed.

There is a high probability that the independent variables are multi-collinear. To eliminate as much of this as possible, the variance inflation factor (VIF)¹⁰ was examined. After eliminating [the coefficients with high p-value](#), the VIF [was](#) required to be less than 5. [V](#), [the values](#) for this analysis tended to be greater than 10,000 to begin with, and drop perceptibly as highly multi-collinear coefficients [were](#) excluded.

[Table 8](#) ~~Table 8~~ summarizes the independent variables used in the VMT regression. The “Number of Times Used in Combination” [column](#) indicates the number of times each variable is statistically significant and non-collinear for either the term itself, the square of the term, and/or an interaction term with another independent variable. Note that the variables highlighted in light grey [we are ones that are](#) not used in this regression because they [we are](#) either statistically insignificant and/or [are very](#) collinear with the other variables. The entire set of cross terms used in the models with their coefficients and values can be found in Table 9: Regression Coefficients for VMT Model [on the next page](#). [Note that there is no significant relationship with median rooms per housing unit \(also retail gravity and local job density\) this result leads to a need of only one model run per household type since there is not dependence on tenure.](#)

Commented [JMG9]: This is the only place this is documented; I need some help understanding so we can clarify (I realize this is taken directly from the documentation from Version 1). E.g., is the sentence beginning “To reduce any bias...” an elaboration of what the analysis consisted of? And what portion of the 8 percent is compensating for the vehicle age thing versus “any other bias that may occur”?

Commented [JMG10]: Can we include actual numbers for this?

¹⁰ For a definition of VIF see http://en.wikipedia.org/wiki/Variance_inflation_factor.

Using the LAIM to Generate the Location Affordability Index (LAI)

I. Modeling Transportation Behaviors and Housing Costs

To hone in on the built environment's influence on the balance between transportation and housing costs, the exogenous household variables (income, household size, and commuters per household) are set at fixed values (i.e., the "selected household") in the Model's outputs to control for any variation they

might cause. By establishing and running the model for a “selected household,” any variation observed in housing and transportation costs may be attributed to place and location, rather than household characteristics.

Commented [JMG11]: Move or delete

I. Modeling Transportation Behaviors and Housing Costs

The model was run for the eight household types in the [Location Affordability Index \(LAI\)](#), each characterized by income, household size, and number of commuters (the same built environment inputs were used each time). -These household types are enumerated in [Table 10](#)~~Table 7~~. They are not intended to match the characteristics of any particular family.- Rather, they were selected to meet the needs of a variety of users, including consumers, planning agencies, real estate professionals, and housing counselors. The incomes used for seven of the eight household types are based on the median household income for each Combined Base Statistical Area (CBSA) covered by the index, [or in the case of rural counties the median household income for the county](#), making the results regionally specific (see [Table 10](#)~~Table 7~~). It was run [for both owner and renter tenure not only for each type, but also by tenure for each type, resulting in a somewhat more complicated but interesting results.](#)

Commented [JG12]: Please elaborate on this

Commented [PH13]: I think Table 11 should elaborate enough.

Table 10: LAI Household Types

Formatted Table

Household Type	Income	Size	Number of Commuters
Median-Income Family	MHHI	4	2
Very Low-Income Individual	National poverty line	1	1
Working Individual	50% of MHHI	1	1
Single Professional	135% of MHHI	1	1
Retired Couple	80% of MHHI	2	0
Single-Parent Family	50% of MHHI	3	1
Moderate-Income Family	80% of MHHI	3	1
Dual-Professional Family	150% of MHHI	4	2

MHHI = Median household income for a given ~~CBSA region area~~ (CBSA or County).

The following steps were ~~taken used in to~~ running the SEM model for each household type:

1. It was applied to both owners and renters. This was done by using the database values for each block group for all the variables that apply to the other tenure (i.e., renters when running owner household, and owners when running renter households – see [Table 11](#)).
2. The VMT model was run for each ~~tenure and~~ household type ([note that the final VMT model has no dependence on tenure – see Table 11](#)).
3. The model SMOC was evaluated and adjusted using the following criteria: if the value was less than the 10 percentile, overwrite the modeled value with the 10 percentile value; if over the 90 percentile, overwrite modeled value with the 90 percentile value.
4. The modeled gross rent was evaluated and modified in the same way as step 3
5. Calculate the transportation cost, for each household type and tenure, using the cost developed for LAI Version 1, but multiply by an inflation factor to determine 2012 dollars from the 2010 calculations.
6. Put costs together with the ratio of each household type income and integrate into the database.

6.

Table 11: Household Variables used in SEM and VMT Model Runs

Modeled Variable	Owner Household Variables ¹¹	Renter Household Variables ¹²
Autos/HH Owners, SMOC and Owners	Values from Table 10	Values from renter households in block group
Autos/HH Renters, Gross Rent and Transit %J2W Renters	Values from owner households in block group	Values from Table 10
VMT Owners	Values from Table 10	NA
VMT Owners	NA	Values from Table 10

Some notable differences between LAI Version 1 and LAI Version 2 resulting from advances in LAIM Version 2:

1. **By not including residuals back into the modeled housing costs, large errors from the ACS are not reintroduced.**

In LAI Version 1, once the housing costs were estimated the residual from the fit was added back into the value. A third-party review of LAI Version 1¹³ suggested this measure to account for different quality of housing stock and intangibles not being modeled, but this increased the variability of the results because it included the large measurement errors from the ACS. Because new measures of housing quality have been included in the SEM model, reintroduction of the large ACS measurement error is avoided. As the SEM model used in LAI Version 2 includes variables which measure housing quality (i.e., rooms per dwelling unit, fraction of detached single family houses, and fraction of renters in the neighborhood), this source of variation is avoided. The SEM modeled values for household type 1 are overall consistent with those of LAI Version 1 (accounting for a small increase in their values) and show less variation as a result.

2. **Different transportation costs are modeled by tenure for each of the eight household types.**

The advantage of including tenure into the model is that it delivers a better estimate of transportation cost for renters versus owners.

3. **The My Transportation Cost Calculator (MTCC) now includes a progressively more accurate estimate of the users' housing and transportation costs.**

A new text box on each tab of the calculator takes advantage of the SEM using the progression of choices made by the user.

4. **National coverage includes rural areas**

SEM allows transit mode share to be simultaneously an explanatory and a response variable. The reduction in the number of input (exogenous) variables reduces the goodness of fit for the places where explicit transit supply data was available, but enhances the simplicity of the model,

¹¹ Household Income Owners, Household Size Owners, and Commuters per Household Owners

¹² Household Income Renters, Household Size Renters, and Commuters per Household Renters

¹³ Econsult Solutions conducted a third-party review of the LAIM Version 1 to assess the validity of the model and provide recommendations for potential improvements.

Housing and Transportation Affordability Initiative

making it possible to develop only one model for all census block groups (both urban and rural) for the entire country.

II. Transportation Cost Calculation

As discussed, LAIM Version 2 estimates three components of travel behavior: auto ownership, auto use, and transit use. To calculate total transportation costs, each of these modeled outputs is multiplied by a cost per unit (e.g., cost per mile) and then summed to provide average values for each block group. This operation is performed for the estimates generated for each of the [eight](#) household types.

A. Auto Ownership and Auto Use Costs

The Consumer Expenditure Survey (CES) from the U.S. Bureau of Labor Statistics is the basis for the auto ownership and auto use cost components of the LAI Version 2. Research conducted by Diane Schanzenbach, PhD and Leslie McGranahan PhD, which included a range of new and used autos, examined expenditures based on the 2005-2010 waves of the CES. This research advanced the effort to overcome limitations of other measures that focused primarily on autos less than five years old. Based on the research, expenditures are represented in inflation-adjusted 2010 dollars using the Consumer Price Index for all Urban Consumers (CPI-U). Expenses are segmented by five ranges of household income (\$0-\$20,000; \$20,000-\$40,000; \$40,000-\$60,000; \$60,000-\$100,000; and, \$100,000 and above) and applied to the modeled autos per household and annual VMT for the appropriate income range. LAI Version 2 uses an additional inflation factor of 1.052913¹⁴ to adjust to 2012 dollars.

Expenditures related to the purchase and operation of cars and trucks are divided into five categories:

- Average annual service flow value¹⁵ from the time the vehicle was purchased to the time the consumer responded to the CES;
- Average annual finance charge paid;
- Ownership Costs: cost of continuing to own a purchased vehicle even if it is not driven;
- Drivability Costs: cost of keeping the vehicle in drivable shape, e.g. maintenance and repairs; and
- Driving Costs: cost of the fuel used to drive the vehicle.

Table ~~124241~~: Per-Vehicle Costs by Income Group ~~Among~~ Households with at Least One Vehicle

Income group number and range	Average Annual Service Flow (1)	Finance Charges (2)	Per vehicle (fixed) ownership costs (3)	Per vehicle (variable) drivability costs (4)	Per vehicle fuel costs (5)	Number of vehicles (6)	Average Ratio drivability to fuel costs (7)
1 (\$0-\$20,000)	\$2,396	\$73	\$657.3	\$400.8	\$1,182.0	1.4	0.34
2 (\$20,000-\$40,000)	\$2,478	\$133	\$732.0	\$421.1	\$1,369.5	1.6	0.31
3 (\$40,000-\$60,000)	\$2,586	\$182	\$755.6	\$458.8	\$1,494.2	1.9	0.31

¹⁴ http://www.bls.gov/data/inflation_calculator.htm

¹⁵ Service flow is the average annual dollar amount of depreciation the vehicle has lost over the time of ownership.

Housing and Transportation Affordability Initiative

4 (\$60,000-\$100,000)	\$2,727	\$211	\$758.6	\$477.6	\$1,552.8	2.2	0.31
5 (\$100,000 & above)	\$3,139	\$201	\$836.6	\$593.1	\$1,635.6	2.5	0.36
Overall average	\$2,717	\$165	\$752.5	\$474.5	\$1,460.9	1.9	0.32

The calculation of auto cost:

$$Cost = A * (V_{sf} + V_{fc} + V_{fixed}) + \left(\frac{VMT}{MPG} \right) * G * (1 + R)$$

Where

A = Modeled autos per household

V_{sf} = Per vehicle service flow cost from ~~Table 12~~~~Table 12~~ ~~Table 11~~ (1) – for the appropriate income group

V_{fc} = Per vehicle finance charge from ~~Table 12~~~~Table 12~~ ~~Table 11~~ (2) – for the appropriate income group

V_{fixed} = Per vehicle (fixed) ownership cost from ~~Table 12~~~~Table 12~~ ~~Table 11~~ (3) – for the appropriate income group

VMT = the modeled annual household VMT

MPG = the national average fuel efficiency (20.7 mpg for 2008)

G = the cost of gas per gallon (average annual regional cost for 2008 - DOE¹⁶)

R = the Average Ratio drivability to fuel cost from ~~Table 12~~~~Table 12~~ ~~Table 11~~ (7) – for the appropriate income group

B. Transit Use Costs

The ~~2009-2010~~ National Transit Database (NTD) served as the source for transit cost data. Specifically, directly operated and purchased transportation revenue ~~were~~ used.¹⁷ The transit revenue, as reported by each of the transit agencies in the NTD. ~~This~~~~The~~ transit revenue ~~was~~ is then allocated to the CBSA served.

This allocation ~~is~~ based on the percentage of each transit agency's bus and rail stations within the CBSA, and how much service is provided at each stop. Most transit agencies serve only one CBSA; however, there are larger systems that serve multiple CBSAs. For example, if a transit agency has a total of 1000 bus stops and 850 of those stops are located in the primary CBSA (CBSA₁) and 150 stops extend into a neighboring CBSA (CBSA₂), the CBSA₁ receives 85 percent of the transit revenue and the neighboring CBSA₂ receives 15 percent. However, this simple allocation of revenue would not take into account how much service is provided at each stop. ~~To account for service frequency, so for example~~ in the case above, if each bus station in CBSA₁ is served by a bus 1000 time a week (about a bus every 10 minutes) and ~~the~~ bus stations in CBSA₂ are served 200 time a week (a little more than once an hour) the fraction of the revenue for CBSA₁ = (1000*1000)/(1000*1000 + 200*85) = about 98 percent, ~~so~~ CBSA₂ ~~would~~ only be allocated 2 percent. Neither of these allocation methods ~~seem are~~ perfect, ~~since as~~ one can assume that low frequency buses from another CBSA might have higher revenue per trip, thus ~~underestimating~~ CBSA₂'s revenue ~~being under estimates~~ in the first method. In order to minimize this discrepancy, the LAIM allocates revenue from each transit agency ~~by~~ using the weighted average of ~~these~~ two methods.

¹⁶ <http://www.eia.gov/petroleum/gasdiesel/>

¹⁷ Demand response revenue is not factored into this analysis.

Housing and Transportation Affordability Initiative

To estimate average household transit costs, each metropolitan area's estimated total transit revenue is ~~then~~ allocated to block groups based on the modeled value of the percentage of transit commuters and the total households within each block group. ~~This~~ is done by calculating the number of transit commuters for each block group, summing across block groups to estimate the total number of transit commuters in the metropolitan area, and then allocating the metro-wide transit revenue to block groups according to the proportion of the region's commuters living in each. The average household transit cost for each block group is then derived by dividing that block group's allocation of transit revenue by number of households.

This same method of allocating regional transit revenues to block groups is ~~also~~ used for allocating transit trips. Using the overall unlinked trip numbers also reported to the NTD, the average number of household transit trips for each block group is estimated by finding the total number of annual trips in each metropolitan area and allocating them proportionally to block groups based on number of households and the percent of journey to work trips.¹⁸

There are a number of metropolitan areas without sufficient information on transit stop locations and/or no revenue listed in the NTD. The average from the allocation calculation described in the previous paragraph is used for these metropolitan areas. The average transit costs are then allocated to the block group level based on the percentage of transit commutes and household commuter counts. The end result is an average household transit cost at the block group level.

¹⁸ This normalization method assumes that the transit use for the journey to work is a good surrogate for overall transit use.

Housing and Transportation Affordability Initiative

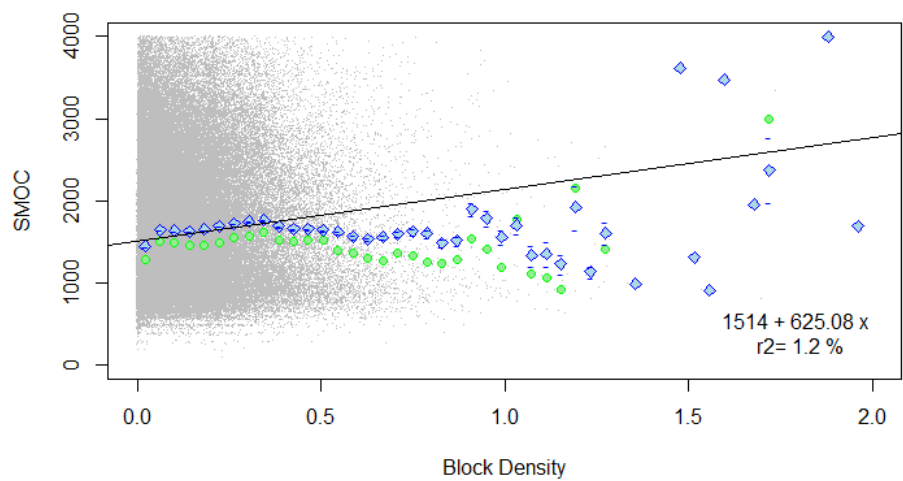

Appendices

Appendix A: Scatter Plots of Endogenous Variables vs. an Example Exogenous Variable

The following plots show the relationships between some of the exogenous variables and the endogenous variables. Note that in each plot there are approximately 200,000 points, depending on the data suppression in the ACS. Each plot has the following features:

- Small grey dots – values for each census block group where there is valid data (i.e. no ACS data suppression),
- Blue diamonds with blue dashed above and below – mean value of the y variable in 50 bins of the x variable, and the blue lines represent the standard error on the mean (when there is no lines this indicates that there are only one block group in this bin),
- Solid green circles – median value of the y variable in 50 bins of the x variable,
- Black line – the linear fit of the y variable with the x variable (note that for many this shows how non-linear many of these relationship are) and
- Text in lower right corner – the equation for the line and the R^2 of the linear fit.

Appendix B:
Path Diagrams

~~Error! Reference source not found.~~ ~~Error! Reference source not found.~~ Figure 5 and Figure 6 are different graphical representations that show the strength of the relationships between all the variables in the SEM fit. The color is either:

- Green – indicating that the relationship is positive, i.e., as Income goes up SMOC increases
- Red – indicates that the relationship is negative, i.e., as employment gravity goes up auto ownership goes down.

The width and darkness of the line indicates the strength of the relationship: wider darker lines indicate strong relationships while thinner lighter lines indicate weaker relationships. The path diagram illustrated in ~~Figure 5~~ ~~Figure 5~~ shows the values of the standardized variables used for LAIM Version 2 (~~Figure 6~~ ~~Figure 6~~ is the same diagram but with a different layout).
